Your doctor is one of a growing number of surgeons offering da Vinci Surgery for Uterine Fibroids.

The Condition(s):
Uterine Fibroids

A uterine fibroid is a common type of benign (non-cancerous) tumor that develops within the uterine wall. Uterine fibroids occur in up to one third of all women and are actually the leading reason for hysterectomy (removal of the uterus) in the United States. Uterine fibroids occur in 20-40% of all women during reproductive years. Uterine fibroids may grow as a single tumor or clusters. They often increase in size and frequency with age, but may also revert in size after menopause. While not all women with fibroids experience symptoms, these may include excessive menstrual bleeding, pelvic pain and difficulty getting pregnant.

Fibroid embolization is a newer, non-invasive treatment available but, there are limited studies showing its long-term success.

Another approach, laparoscopic myomectomy, offers a minimally invasive alternative to open surgery but is usually not an option for women with large fibroids, multiple fibroids or with fibroids in difficult-to-reach areas.²

For women who want a uterine-sparing procedure, da Vinci Myomectomy offers numerous potential benefits over open abdominal surgery, including:

- Significantly less pain²
- Less blood loss and need for blood transfusions²
- Shorter hospital stay²
- Faster recovery and quicker return to normal activities²
- Less scarring²

As with any surgery, these benefits cannot be guaranteed, as surgery is patient- and procedure-specific.

Together, da Vinci technology allows your doctor to perform complex procedures through just a few tiny openings. As a result, you may be able to get back to life faster without the usual recovery following major surgery.

The da Vinci System has been used successfully worldwide in hundreds of thousands of procedures to date.

The Treatment: Myomectomy

A common alternative to hysterectomy for fibroids is myomectomy, the surgical removal of fibroid tumors and a procedure considered standard-of-care for removing fibroids and preserving the uterus. It therefore may be recommended for women who wish to become pregnant.

Myomectomy is most often performed through a large abdominal incision. After removing each fibroid, the surgeon repairs the uterus to minimize potential bleeding, infection and scarring. Proper repair is critical to reducing the risk of uterine rupture during a future pregnancy.

Fibroid embolization is a newer, non-invasive treatment available but, there are limited studies showing its long-term success.

Another approach, laparoscopic myomectomy, offers a minimally invasive alternative to open surgery but is usually not an option for women with large fibroids, multiple fibroids or with fibroids in difficult-to-reach areas.

If your doctor recommends surgery to treat uterine fibroids, you may be a candidate for a uterine-preserving, minimally invasive procedure – da Vinci Myomectomy. Using the most advanced technology available, da Vinci Myomectomy enables surgeons to perform this delicate operation with unmatched precision, vision and control using only a few small incisions.

For women who want a uterine-sparing procedure, da Vinci Myomectomy offers numerous potential benefits over open abdominal surgery, including:

- **Significantly less pain**
- **Less blood loss and need for blood transfusions**
- **Shorter hospital stay**
- **Faster recovery and quicker return to normal activities**
- **Less scarring**

As with any surgery, these benefits cannot be guaranteed, as surgery is patient- and procedure-specific.

The Enabling Technology: da Vinci Surgical System

The da Vinci Surgical System is designed to provide surgeons with enhanced capabilities, including high-definition 3D vision and a magnified view. Your doctor controls the da Vinci System, which translates his or her hand movements into smaller, more precise movements of tiny instruments inside your body. Though it is often called a “robot,” da Vinci cannot act on its own. Instead, the surgery is performed entirely by your doctor.

While clinical studies support the effectiveness of the da Vinci® System when used in minimally invasive surgery, individual results may vary. Surgery with the da Vinci System may not be appropriate for every individual. Always ask your doctor about all treatment options, as well as their risks and benefits.

The Condition(s):
Uterine Fibroids

A uterine fibroid is a common type of benign (non-cancerous) tumor that develops within the uterine wall. Uterine fibroids occur in up to one third of all women and are actually the leading reason for hysterectomy (removal of the uterus) in the United States.¹ Uterine fibroids occur in 20-40% of all women during reproductive years.²

Uterine fibroids may grow as a single tumor or clusters. They often increase in size and frequency with age, but may also revert in size after menopause. While not all women with fibroids experience symptoms, these may include excessive menstrual bleeding, pelvic pain and difficulty getting pregnant.
